

# CS229: Additional Notes on Backpropagation

## 1 Forward propagation

Recall that given input  $x$ , we define  $a^{[0]} = x$ . Then for layer  $\ell = 1, 2, \dots, N$ , where  $N$  is the number of layers of the network, we have

1.  $z^{[\ell]} = W^{[\ell]}a^{[\ell-1]} + b^{[\ell]}$
2.  $a^{[\ell]} = g^{[\ell]}(z^{[\ell]})$

In these notes we assume the nonlinearities  $g^{[\ell]}$  are the same for all layers besides layer  $N$ . This is because in the output layer we may be doing regression [hence we might use  $g(x) = x$ ] or binary classification [ $g(x) = \text{sigmoid}(x)$ ] or multiclass classification [ $g(x) = \text{softmax}(x)$ ]. Hence we distinguish  $g^{[N]}$  from  $g$ , and assume  $g$  is used for all layers besides layer  $N$ .

Finally, given the output of the network  $a^{[N]}$ , which we will more simply denote as  $\hat{y}$ , we measure the loss  $J(W, b) = \mathcal{L}(a^{[N]}, y) = \mathcal{L}(\hat{y}, y)$ . For example, for real-valued regression we might use the squared loss

$$\mathcal{L}(\hat{y}, y) = \frac{1}{2}(\hat{y} - y)^2$$

and for binary classification using logistic regression we use

$$\mathcal{L}(\hat{y}, y) = -(y \log \hat{y} + (1 - y) \log(1 - \hat{y}))$$

or negative log-likelihood. Finally, for softmax regression over  $k$  classes, we use the cross entropy loss

$$\mathcal{L}(\hat{y}, y) = - \sum_{j=1}^k \mathbf{1}\{y = j\} \log \hat{y}_j$$

which is simply negative log-likelihood extended to the multiclass setting. Note that  $\hat{y}$  is a  $k$ -dimensional vector in this case. If we use  $y$  to instead denote the  $k$ -dimensional vector of zeros with a single 1 at the  $l$ th position, where the true label is  $l$ , we can also express the cross entropy loss as

$$\mathcal{L}(\hat{y}, y) = - \sum_{j=1}^k y_j \log \hat{y}_j$$

## 2 Backpropagation

Let's define one more piece of notation that'll be useful for backpropagation.<sup>1</sup> We will define

$$\delta^{[\ell]} = \nabla_{z^{[\ell]}} \mathcal{L}(\hat{y}, y)$$

We can then define a three-step “recipe” for computing the gradients with respect to every  $W^{[\ell]}, b^{[\ell]}$  as follows:

1. For output layer  $N$ , we have

$$\delta^{[N]} = \nabla_{z^{[N]}} \mathcal{L}(\hat{y}, y)$$

Sometimes we may want to compute  $\nabla_{z^{[N]}} \mathcal{L}(\hat{y}, y)$  directly (e.g. if  $g^{[N]}$  is the softmax function), whereas other times (e.g. when  $g^{[N]}$  is the sigmoid function  $\sigma$ ) we can apply the chain rule:

$$\nabla_{z^{[N]}} \mathcal{L}(\hat{y}, y) = \nabla_{\hat{y}} \mathcal{L}(\hat{y}, y) \circ (g^{[N]})'(z^{[N]})$$

Note  $(g^{[N]})'(z^{[N]})$  denotes the elementwise derivative w.r.t.  $z^{[N]}$ .

2. For  $\ell = N - 1, N - 2, \dots, 1$ , we have

$$\delta^{[\ell]} = (W^{[\ell+1]\top} \delta^{[\ell+1]}) \circ g'(z^{[\ell]})$$

3. Finally, we can compute the gradients for layer  $\ell$  as

$$\begin{aligned} \nabla_{W^{[\ell]}} J(W, b) &= \delta^{[\ell]} a^{[\ell-1]\top} \\ \nabla_{b^{[\ell]}} J(W, b) &= \delta^{[\ell]} \end{aligned}$$

where we use  $\circ$  to indicate the elementwise product. Note the above procedure is for a single training example.

You can try applying the above algorithm to logistic regression ( $N = 1$ ,  $g^{[1]}$  is the sigmoid function  $\sigma$ ) to sanity check steps (1) and (3). Recall that  $\sigma'(z) = \sigma(z) \circ (1 - \sigma(z))$  and  $\sigma(z^{[1]})$  is simply  $a^{[1]}$ . Note that for logistic regression, if  $x$  is a column vector in  $\mathbb{R}^{d \times 1}$ , then  $W^{[1]} \in \mathbb{R}^{1 \times d}$ , and hence  $\nabla_{W^{[1]}} J(W, b) \in \mathbb{R}^{1 \times d}$ . Example code for two layers is also given at:
